Dev_Agent

Agent that spawn sub agents, learn new skills, and ship your code.

Anish K

Motivation

AI Agents can write code, but we still don’t trust it to build and run software on its own.

01 **One-size-fits-all agents don’t fit real projects.** A frontend, an ML pipeline and a DevOps setup need different expertise, and fixed agent roles can’t adapt to each.

02 **Agents get stuck at the edge of their knowledge.** When a task falls outside their toolkit, they stall instead of learning how to do it.

03 **Running AI-written code on your own machine is a risk.** Untrusted code needs real isolation, not just a permission prompt.

04 **Developers want a choice in how much to delegate.** Sometimes you want full automation, and sometimes you want to direct a single specialist.

We need agents that adapt to the task, extend their own abilities, and execute safely.

The Core Idea

A self-extending developer agent that runs safely at scale.

01 **Dynamic subagent creation:** Specialist subagents (frontend, backend, DevOps, ML...) are spawned on demand to fit each request

02 **Dynamic skill creation and selection:** The agent writes new reusable skills when a task needs them, and picks from existing ones when they already fit

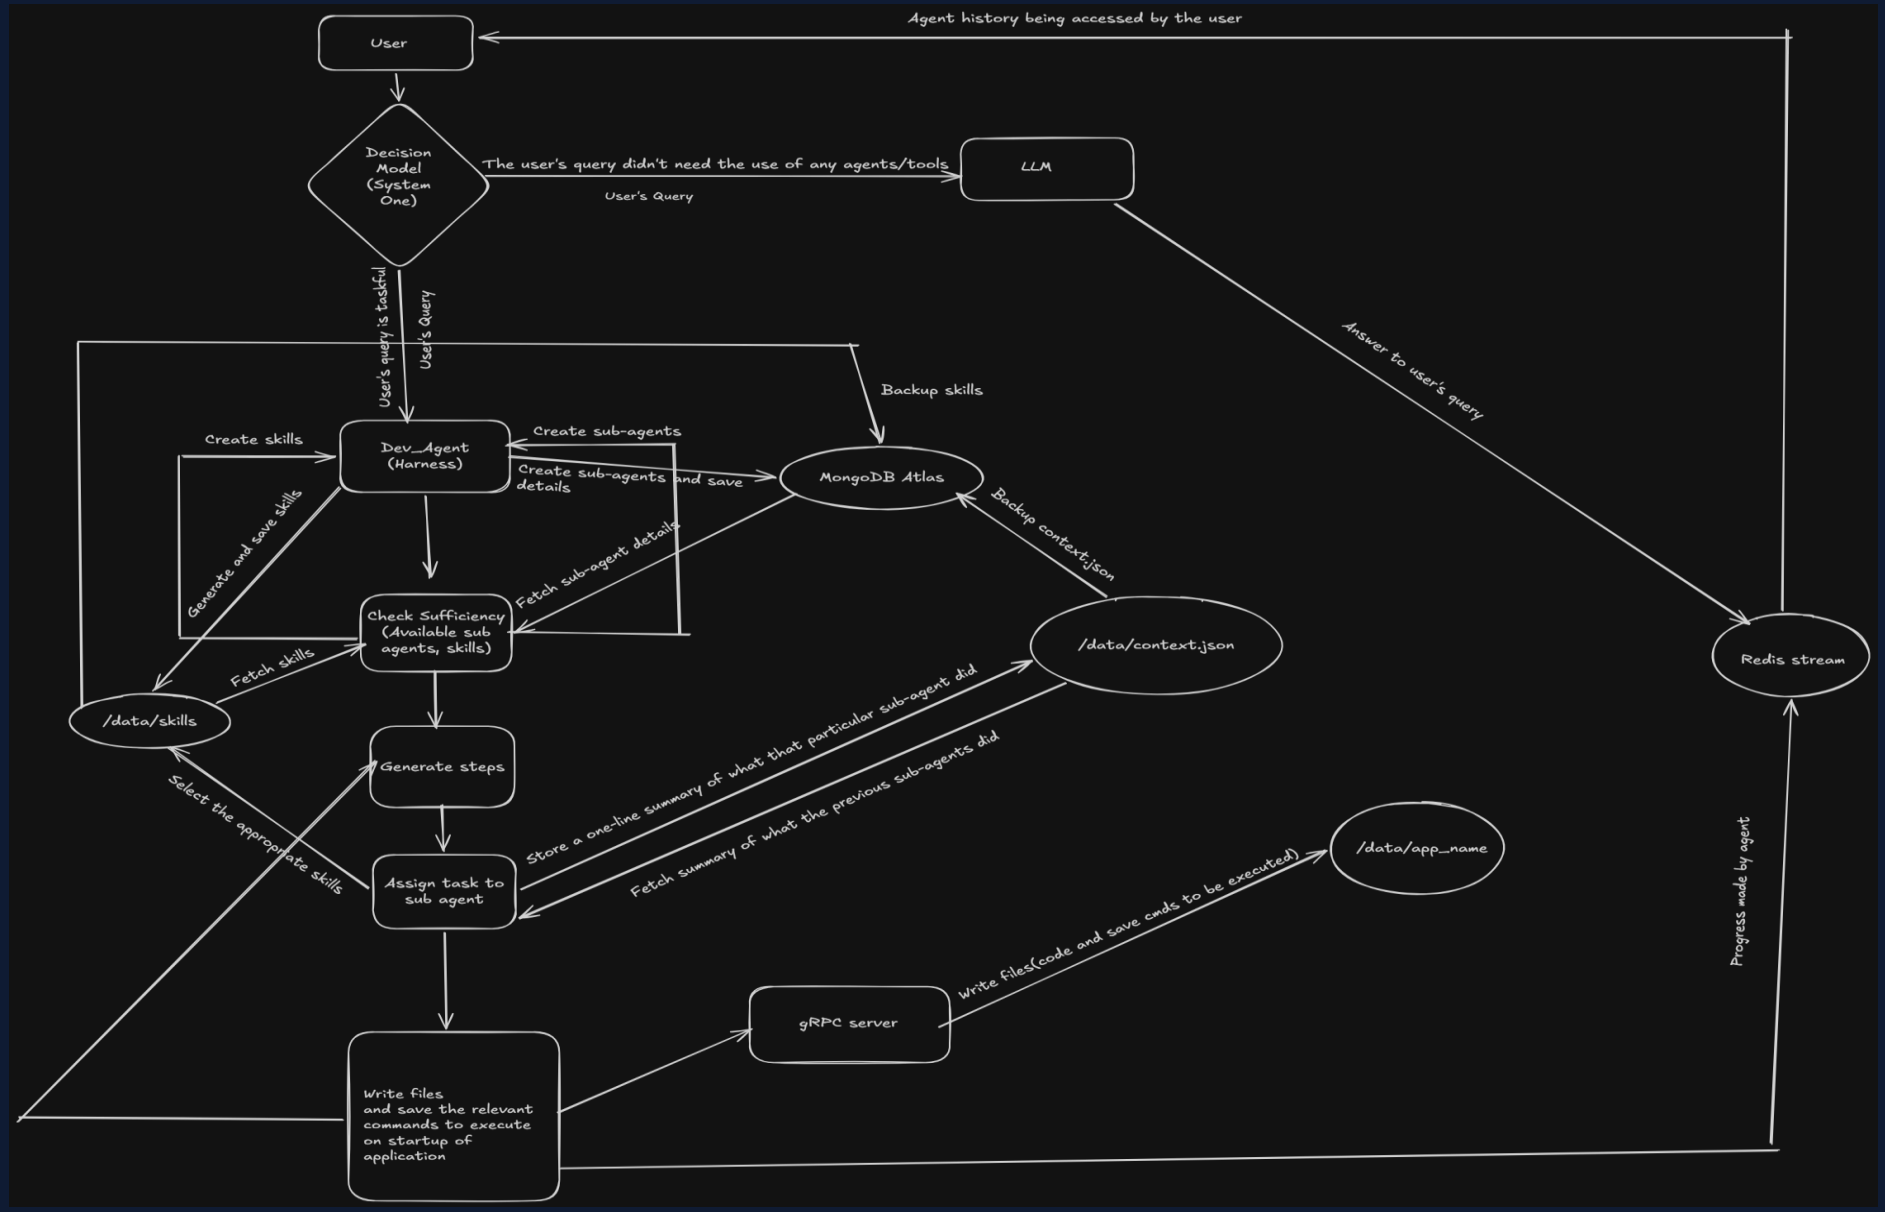

03 **Sandboxed hosting on Kubernetes:** The agent runs on a K8s cluster with gVisor as the runtime, so AI-written code never touches the host machine.

04 **Multiple user sessions:** Users can open several sessions and send requests to the agent in each one

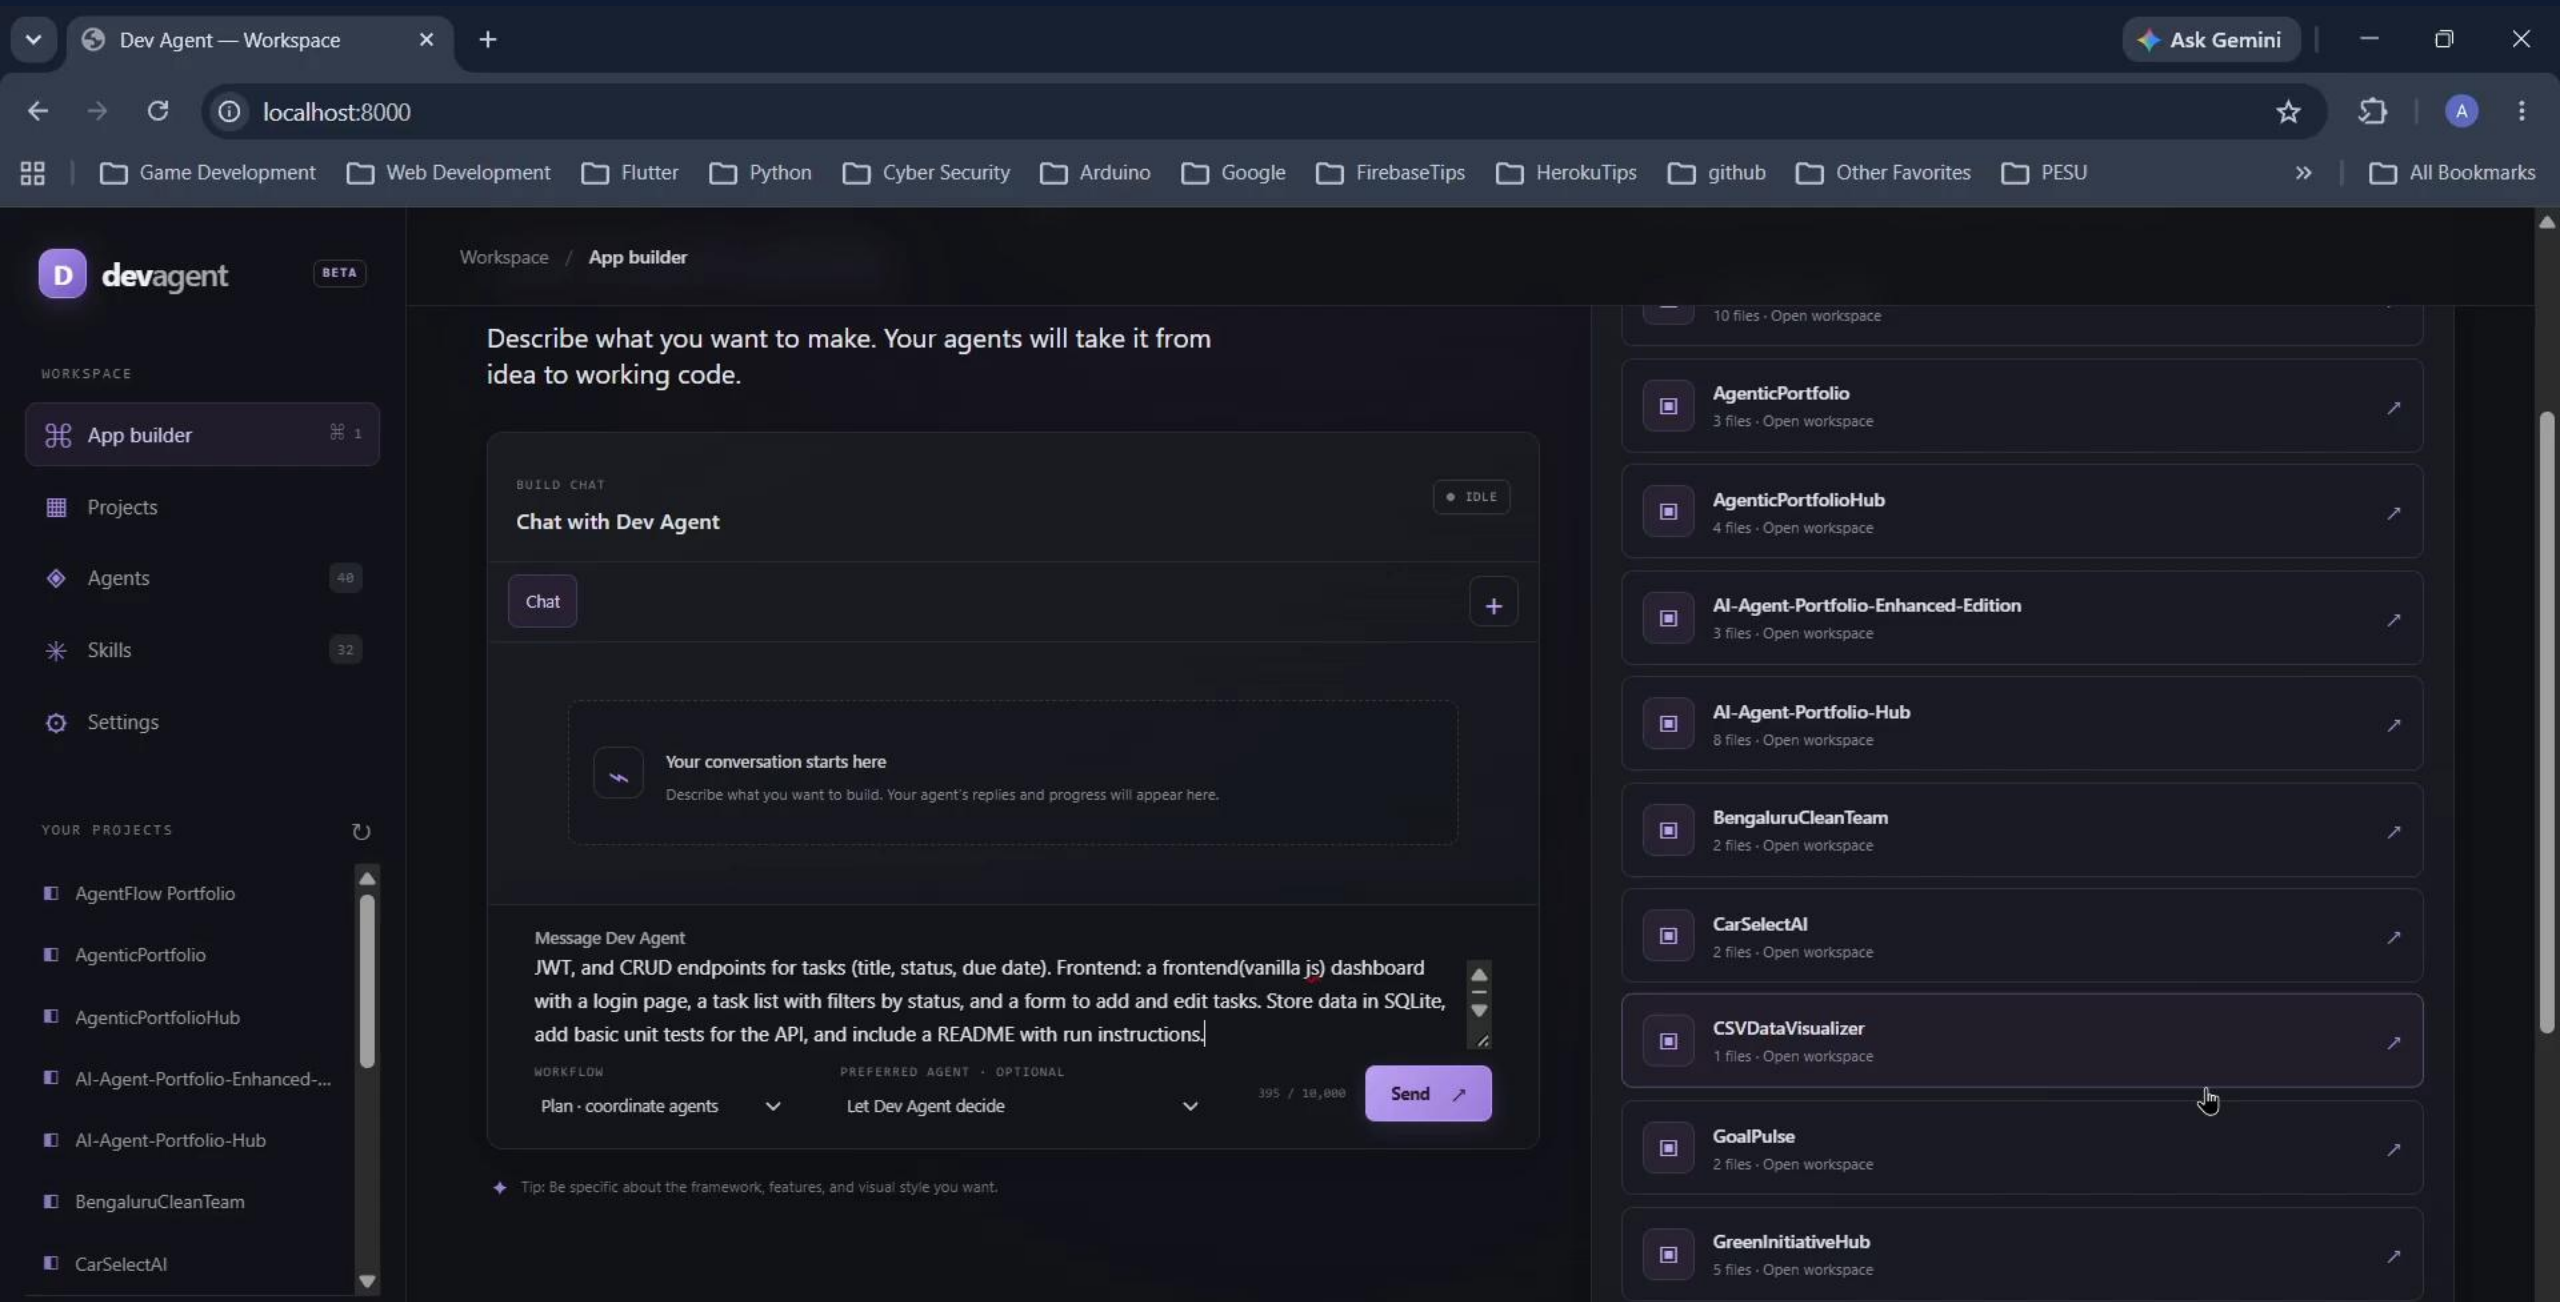

Tech Stack: Python, Go, gRPC, Kubernetes, LangGraph, Redis, MongoDB

Specialist agents that grow their own skills, running in a gVisor sandbox on Kubernetes, with as many sessions as you need.

Agent Architecture

JWT, and CRUD endpoints for tasks (title, status, due date). Frontend: a frontend(vanilla js) dashboard with a login page, a task list with filters by status, and a form to add and edit tasks. Store data in SQLite, add basic unit tests for the API, and include a README with run instructions.

Future Improvements

1. **Live app interaction over WebSockets:** Users can use the generated application in real time, streamed from the sandbox to their browser over WebSockets.
2. **Autonomous Debugging:** During the execution of the program, if an error occurs let the agent analyse it and make appropriate changes.
3. Integration with RepoLens MCP: Giving more context to the agent on how the current project works and what modules must be modified in order to suit the user’s requirements.
